Dear Nalinaa,

RE: Rose Dawson DOB: 11/08/2015

I had telehealth consultation with Daniela, Rose's mother.

I have also had phone discussions with Lachlan, Rose's dad and a neuroradiologist.

Following our discussions we decided to reduce Desmopressin to 120 mg bd, however, I find from Daniella that they have further reduced Desmopressin to his previous dose of 120 mg every evening, over the last week or so. Daniella seems to think this is working well in managing urine frequency and volume during the night.

Lachlan has also been investigating this issue of worsening thirst and polyuria that Rose has experienced recently and mentioned dipsogenic polydipsia and I felt he may be referring to primary polydipsia. This is a well-recognised condition and may also have an association with diabetes insipidus and an association with hypothalamic trauma infiltration etc., which may result in altered thirst perception. The chronic excessive fluid intake may lead to reduction in renal medulla concentration gradient and down regulation of aquaporin to channels further leading to hypotonic urine.

There is no denying diabetes insipidus given the historical association and response to Desmopressin, however, I also feel there may be co-existing primary polydipsia during the daytime contributing.

Pathology performed on the 21st Nov shows Na of 142 nmols/L and K level is 4.2 mmols.

Rose's parents have already instituted some measures such as having smaller quantities of water fluid and using ice blocks of frozen icy poles to improve thirst but not lead to excessive drinking behaviour.

I will be grateful for your continuing care and have left a follow up appointment open at your or his parents discretion.

Yours sincerely,

Dr Sally Wood
